From 17th Annual SCMR Scientific Sessions
New Orleans, LA, USA. 16-19 January 2014

Background

Aortic valve replacement (AVR) is the definitive treatment for severe symptomatic aortic stenosis (AS). Aortic stenosis is associated with diastolic dysfunction and left atrial (LA) enlargement. After a successful AVR, there is a decrease in LA size but persistence in diastolic dysfunction. We hypothesized that LA function would help link this discordance. Cardiac magnetic resonance (CMR) is the gold standard for assessment of the LA. We therefore aimed to test the effect of AS on LA function and the subsequent effects of an AVR on LA function. We hypothesized that, similar to diastolic function, LA function would not improve post-AVR and that the persistence in LA dysfunction might be related to expansion of the extracellular space.

Methods

A comprehensive CMR exam was performed on 18 patients with isolated AS and without coronary disease pre- and 1 year post-AVR. Results were compared to age- and gender matched healthy controls. Left atrial volumes (LAV) were calculated at the end of ventricular systole (LAVmax), just before atrial contraction (LAV-bac), and at the end of ventricular diastole (LAVmin) using the biplane area-length method. Left atrial passive emptying fraction (LAPEF) defined by $(LAV_{max} - LAV_{bac}) \times 100 / LAV_{max}$, as well as left atrial contractile emptying fraction (LACEF) defined by $(LAV_{bac} - LAV_{min}) \times 100 / LAV_{bac}$ were calculated. T1 measurements were made in the myocardium and blood before and after contrast administration using a Look-Locker

sequence with a gradient echo cine acquisition. The ECV was calculated by comparing the change in the R1 values from blood to myocardium and integrating the hematocrit.

Results

Patients were predominantly male (67%) with a mean age of 61 ± 12 years, and a mean LVEF of $62 \pm 5\%$. Prior to AVR, patients with AS had an increased left ventricular (LV) mass, increased LA volume, reduced LAPEF, and an increased ECV (Table 1). At one year after AVR, there was a marked reduction in LV mass and a decrease in LA volume. However, there was further impairment in LAPEF and a continued increase in the ECV at 1 year post-AVR (Table, Graph). There was a strong inverse association between the LAPEF and the ECV ($r = -0.70$, $p < 0.001$) and a strong inverse association between the decline in LAPEF and the increase in the ECV post AVR ($r = -0.71$, $p < 0.001$).

Conclusions

Severe AS is associated with a reduction in LA passive function. After AVR, LAPEF continues to decline and there was a strong inverse association between LAPEF and the ECV.
